

Parkinsonism

**DR. CLAIRE HINNELL
NEUROLOGIST
MOVEMENT DISORDERS SPECIALIST
SURREY
DECEMBER 20, 2023**

Disclosures

- I **DO NOT** have an affiliation (financial or otherwise) with any for-profit or not-for-profit organizations

Learning Objectives

- To be able to differentiate Parkinson's DISEASE from Parkinson's plus syndromes and parkinsonism
- To be able to describe the implications of a Parkinson's plus condition diagnosis for the patient and family
- To be able to use a practical approach to treatment and care for patients with Parkinson's Plus Conditions

Differentiate Parkinson's DISEASE from Parkinson's plus syndromes

Parkinsonism

- clinical definition of a variety of different underlying pathologies that can cause Parkinson's-like symptoms such as
 - slowing of movement
 - tremor
 - rigidity or stiffness
 - balance problems

Approach to Parkinsonism

Parkinson's Disease

Young onset

Late onset (usually > 60 yrs)

Parkinson's plus syndromes

MSA

PSP

CBS

Herido-degenerative

AD

DLB

FTLD

Huntington's ds

SCA

Wilson's ds

Secondary Causes

NPH

Drugs

Vascular

Inflammatory disorders

CNS infections

Brain tumor

Paraneoplastic

Toxins

Metabolic

Idiopathic PD Diagnosis

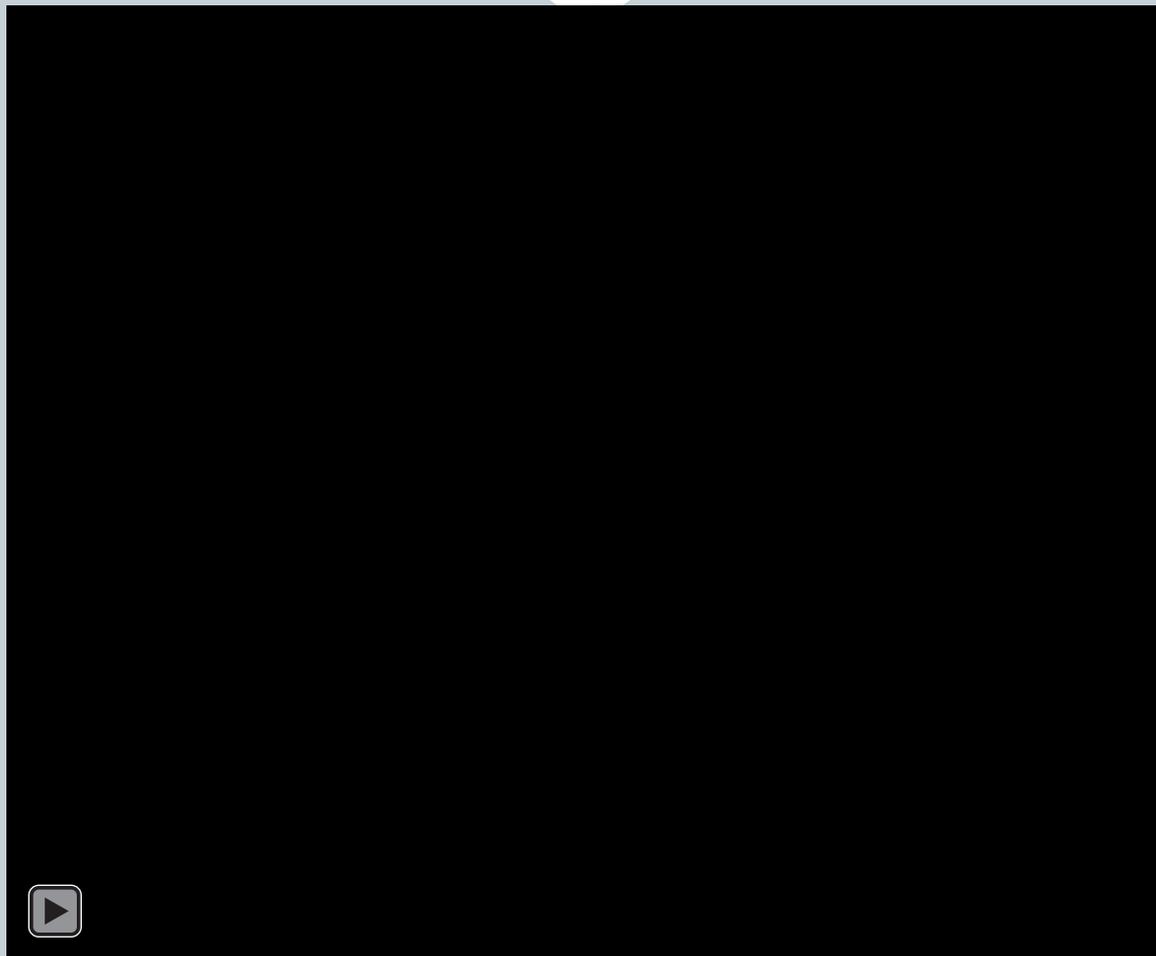

- **Clinical Criteria**
 - Bradykinesia
 - At least one of the following:
 - ✦ Rigidity
 - ✦ 4–6 Hz rest tremor
 - ✦ Postural instability not caused by primary visual, vestibular, cerebellar or proprioceptive dysfunction
 - ***Exclude other causes of parkinsonism**

PD Tremor

- Most common cause of resting tremor
- Insidious onset
- Distal, asymmetric
- Flex/ext elbow, pro/sup forearm, pill rolling fingers
- May have postural or kinetic component if rest tremor is severe

PD tremor

If there's a rest tremor...look for:

■ Associated features:

- Rigidity
- Bradykinesia
- Postural instability

- Gait

- Red flags (Hx and Exam)

Parkinson's Plus Syndromes

- Overall, progression more rapid and survival shorter than PD

Multiple Systems Atrophy

- alpha-synucleinopathy
- MSA-P vs MSA-C
- autonomic dysfunction

Progressive Supranuclear Palsy

- tauopathy
- early falls
- axial issues
- eye movement abnormalities

Corticobasal Syndrome

- tauopathy
- cortical dysfunction

Multiple Systems Atrophy

- onset usually in 6th decade
- 3/100 000 (PD = 1/100)
- variable combination of parkinsonism, cerebellar features and autonomic dysfunction
- often wheelchair bound in 5 yrs
- mean survival 8 yrs (shorter if early autonomic symptoms)

Probable MSA Criteria

Sporadic, progressive adult-onset disease characterized by:

- Autonomic failure involving urinary incontinence plus erectile dysfunction in males, or an orthostatic decrease of blood pressure within 3 minutes of standing by at least 30 mm Hg systolic or 15 mm Hg diastolic AND
- Poorly levodopa-responsive parkinsonism OR
- A cerebellar syndrome

MSA

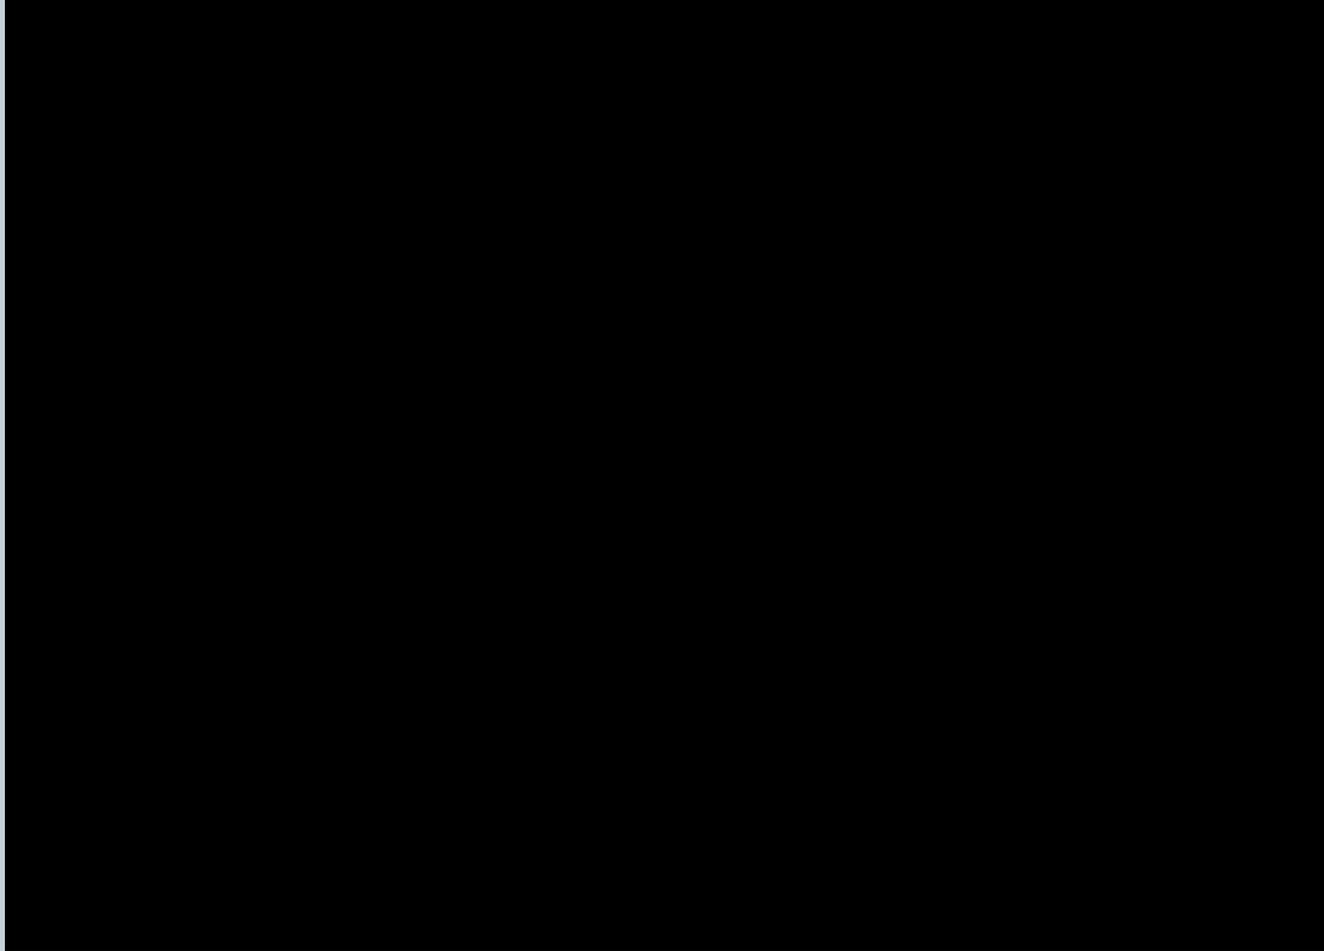

- Autonomic dysfunction
- Parkinsonism (not usually rest tremor)
- Cerebellar dysfunction
- Dysarthria, dysphonia
- Respiratory
 - inspiratory stridor - urgent referrals
- Other
 - Rem sleep disorder
 - Corticospinal tract signs
 - Myoclonus
 - Dystonia
- **Cognitive impairment is uncommon**
- **No family history**

MSA

MSA myoclonus

MSA

Red flags -> think of MSA

- **early/severe autonomic dysfxn
- cerebellar signs
- pyramidal signs
- poor l-dopa response
- rapid progression
- symmetric parkinsonism at onset
- no/little rest tremor
- jerky, myoclonic postural/action tremor
- antecollis, Pisa syndrome, camptocormia
- postural stability decreased early on (but falls at ds onset more suggestive of PSP)
- dysarthria – high-pitched, quivering, soft, breathy
- dysphagia w/in 5 yrs
- orofacial dystonia, esp. perioral
- **involuntary gasping/deep sighing when awake**
- **new or increased snoring**
- **stridor**
- contractures of hands/feet
- cold hands/feet
- pathologic laughter or crying

Progressive Supranuclear Palsy

Progressive Supranuclear Palsy

- onset usually early 60's
- mean survival 6-9 yrs
- 40-50% have early mild response to l-dopa
- tauopathy (like corticobasal degeneration)

Probable PSP Criteria

- gradually progressive
- onset > 40 yrs
- vertical supranuclear palsy and prominent postural instability with tendency to fall in first year of disease onset
- no evidence of other disease that could explain symptoms....whole bunch of exclusion criteria

PSP

- eye abnormalities
- postural instability with falls within 1 yr of onset
- symmetric axial bradykinesia and rigidity
- axial > limb rigidity
- < 10% rest tremor
- eyelid retraction and 'stare'
- eyelid opening apraxia
- retrocollis
- dystonic posturing of hands and feet
- striatal hand deformities
- dysarthria
- dysphagia
- dementia
- NOT usually have REM sleep disorder

PSP

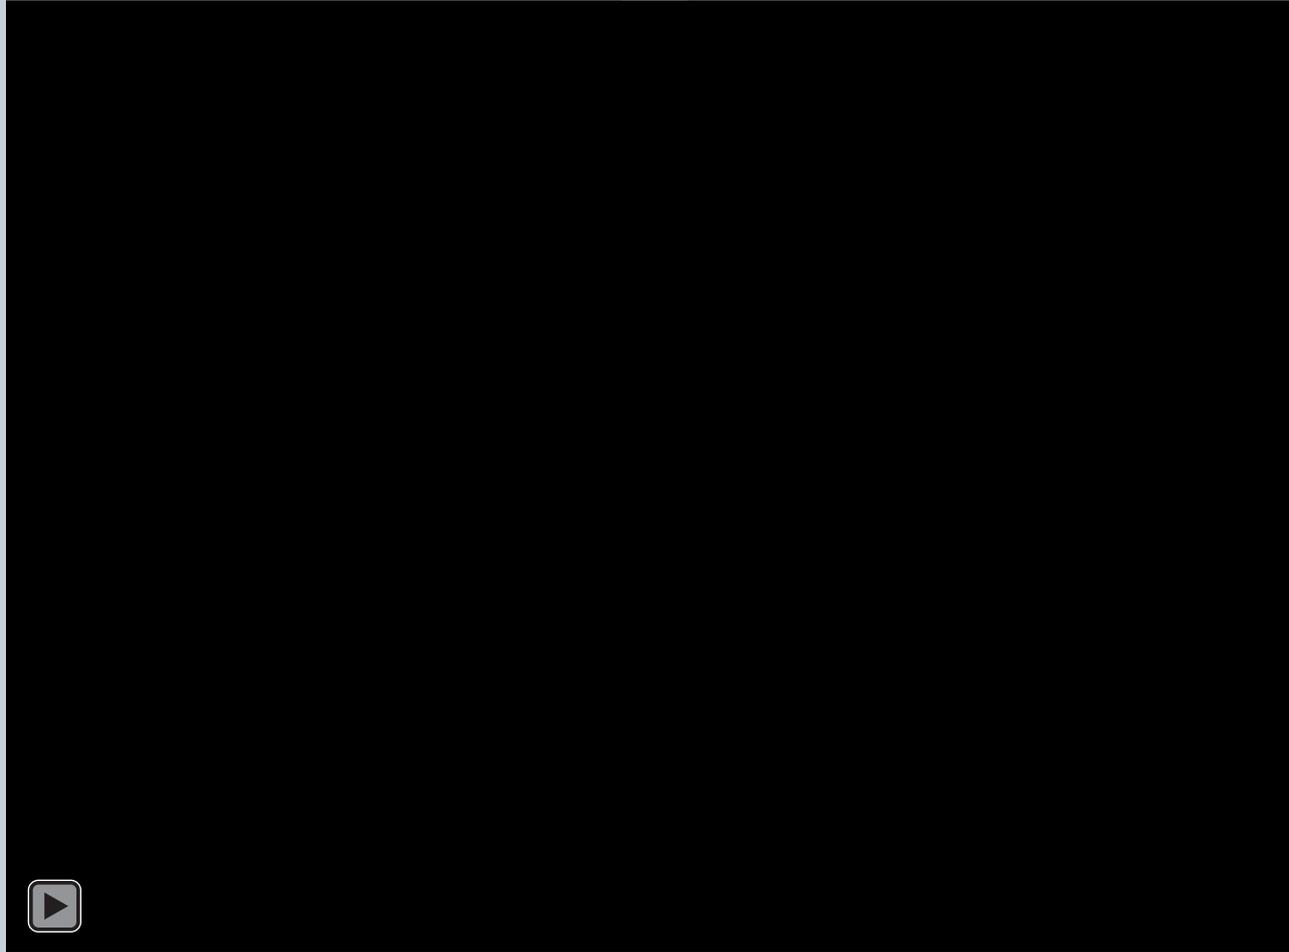

- **Eye abnormalities**
 - vertical gaze abnormalities (reduced OKN, hypometric, palsies)
 - supranuclear eye mvmt abnormalities may not appear for 4-5 yrs
 - slow downward saccades with impaired downward OKN
 - square wave jerks, saccadic intrusions
 - paresis of upgaze
 - apraxia of eyelid opening

 - CBD - difficulties initiating horizontal and vertical saccades, typical of an oculomotor apraxia (whereas PSP has slowed vertical saccades)

Gaze palsy in PSP

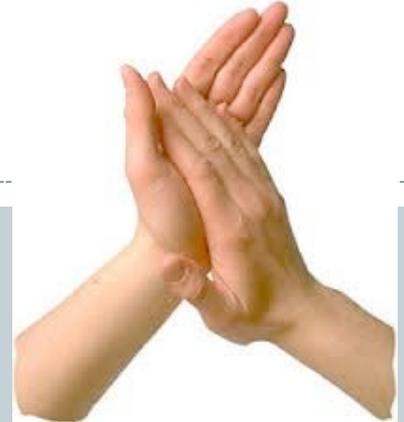

Eyelid opening apraxia

PSP – other signs

- applause sign
- sloppy tie sign
- rocket sign
- falling back in chair ‘en bloc’
- pseudobulbar laughing or crying
- stuttering speech, palilalia

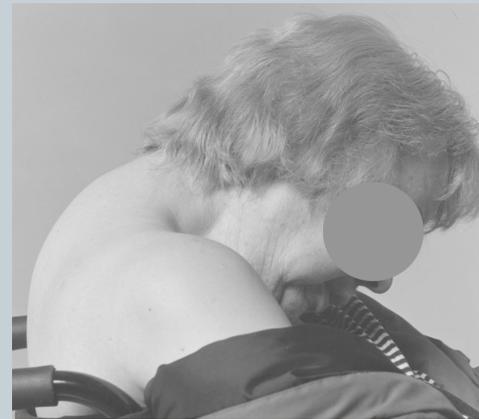

PSP

VS

MSA

Corticobasal Syndrome

Woman attacked by
her own hand!

Corticobasal Syndrome

- onset after 45 yrs
- tau-opathy (like PSP)
- pathology can vary (60% caused by corticobasal degeneration)

Probable Corticobasal Syndrome

- **asymmetric presentation of 2 of**
 - limb rigidity or akinesia
 - limb dystonia
 - limb myoclonus
- **2 of**
 - orobuccal or limb apraxia
 - cortical sensory deficit
 - alien limb phenomena

Corticobasal Syndrome

- asymmetric bradykinesia, rigidity
- cortical sensory loss
- alien limb
- dystonia
- myoclonus
- apraxia (can have enough bradykinesia and dystonia so apraxia not evident)
- visual neglect
- frontal dementia, aphasia (can be cognitively intact at onset while still significant motor signs)
- oculomotor apraxia (difficulty initiating saccades)

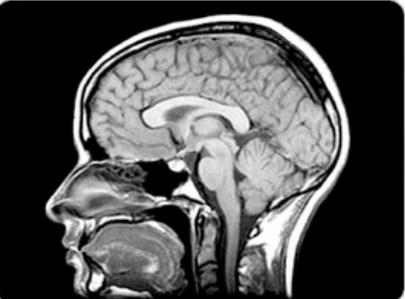

Corticobasal Syndrome

PSP and CBD share many features

- rapid disease progression
- poor levodopa response
- eye movement abnormalities
- cognitive impairment
- pyramidal signs
- dystonia

PD

TAKE HOME

Parkinson Plus Syndromes vs PD

- Poor response to levodopa
- Falls at presentation and early in the disease course
- Symmetry at onset
- Rapid progression (to bilateral disease/imbalance within 3 years)
- Lack of tremor
- Early dysautonomia

Be able to describe the implications of a Parkinson's plus condition diagnosis for the patient and family

- Progression: faster
- Survival: shorter
- Treatment: levodopa less or not effective

Practical approach to treatment and care for patients with Parkinson's Plus Conditions

Approach to Medical Treatment of Parkinsonism

- SYMPTOMATIC
- Trial levodopa if bradykinetic/rigid– up to 1000 mg/day if tolerated
 - may need caution if orthostatic hypotension or cognitive issues/hallucinations
- doesn't work for balance or ataxia

Approach to Medical Treatment of Parkinsonism

- **Cognition**
 - cholinesterase inhibitors (watch for OH)
 - quetiapine (only if really necessary, no evidence for it)
 - clozapine (not commonly used)
 - DLB – neuroleptic sensitivity
- **Sleep**
 - REM sleep behaviours
 - ✦ melatonin > clonazepam
- **Mood**
 - SSRIs

- Dysautonomia
 - excessive sweating
 - urinary issues – mirabegron, solifenacin
 - erectile dysfunction – sildenafil etc.
 - postural hypotension...

Postural hypotension

Approach to Care for Parkinson's Plus Conditions

- **PATIENCE** (cognition can be better than it seems)
- **Swallowing**
 - vigilance
 - PEG discussion
- **Speech**
 - SLP
 - assistive devices
 - amplifiers
- **Falls risk reduction**
 - polypharmacy
 - behavioural strategies
- **Avoid complications**
 - contractures – stretching, careful use of muscle relaxants, botulinum toxin
 - pain (from dystonia and other causes)

Other causes of parkinsonism in LTC

Alzheimer's disease

- most common – hypomimia
- bradykinesia > postural instability > abnormal gait > rigidity
- resting tremor less common
- presence of parkinsonism increases proportionally with progression of AD and cognitive & functional decline
- presence of parkinsonism - poor prognostic factor with faster cognitive and functional decline

Dementia with Lewy Bodies

- 2nd most common dementia (after AD)
- onset 74 yrs
- M>F
- dementia within first year of parkinsonism
- fluctuating cognition
- visual hallucinations
- parkinsonism -70%

- RBD
- hypersomnolence
- sensitive to low dose antipsychotics

Drug-induced Parkinsonism

- can be indistinguishable from Parkinson's disease
- tends to be symmetric but can have asymmetry of signs
- dose-related s/e effect
- F>M
- increases with advancing age
- onset within 3 mo in 90% but can occur at any time (even years later)
- “reversible” when offending agent reduced or discontinued but reversal can take many months – up to 18 months
- tx
 - taper/stop offending drug, switch to lower D2 affinity
 - anticholinergics
 - amantadine
 - dopaminergic therapy – controversy- unmasking?

Vascular parkinsonism

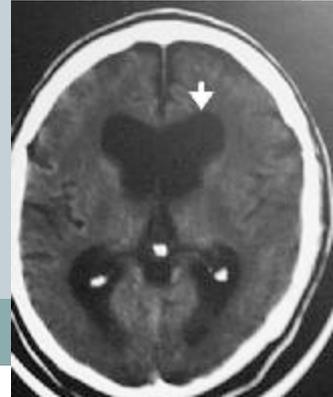

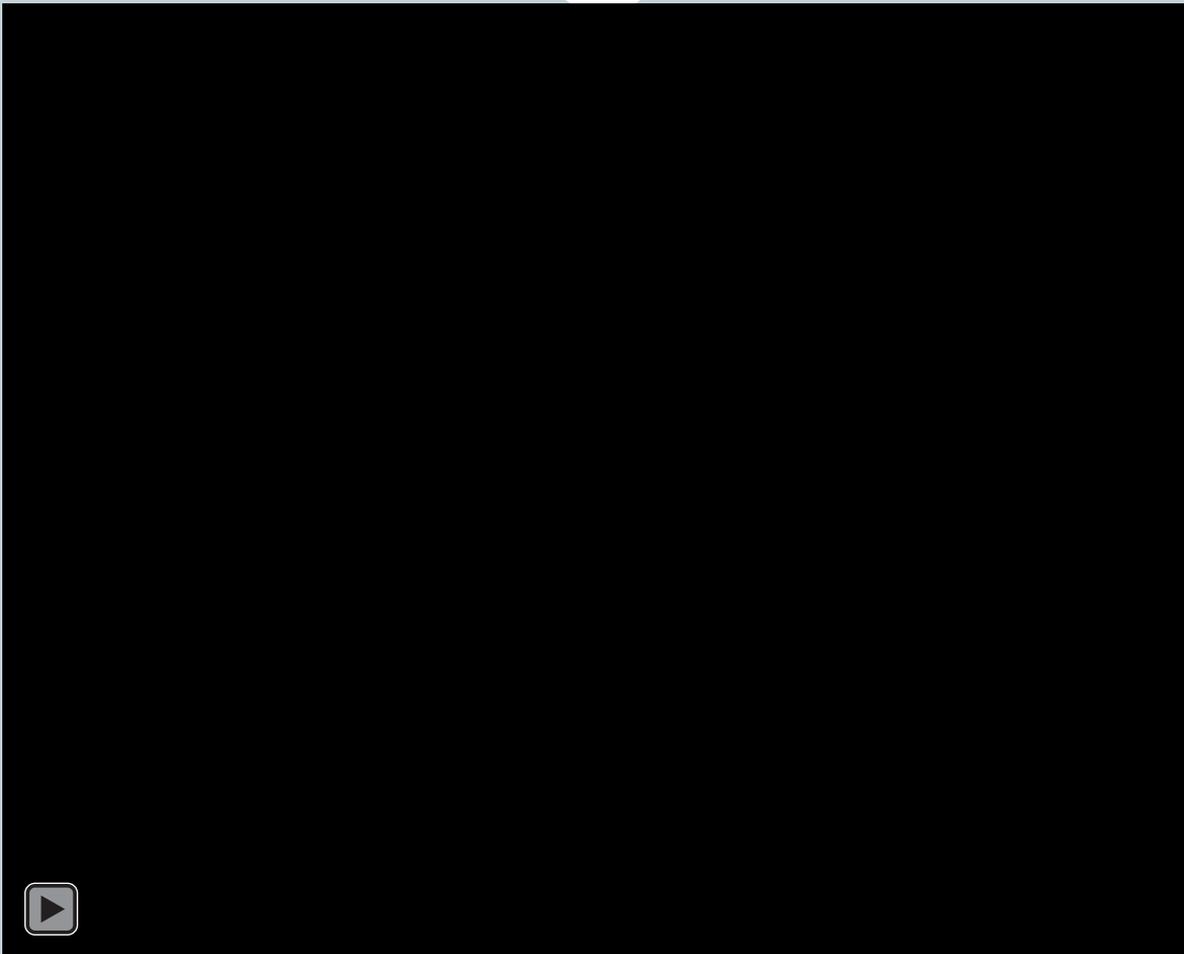

- “lower half parkinsonism”
- major problems with gait initiation, hesitation, freezing, especially with turning
- better once get going
- walking is interrupted by shifting focus
- can reduce freezing with cues
- arms normal speed
- can have asymmetric reduced arm swing
- can try l-dopa, 40% may respond to a degree
- Tx vascular risk factors

Normal Pressure Hydrocephalus

- **Triad:**
 - gait disturbance – small step, magnetic, wide-based, apraxic
 - urinary incontinence (frontal lobe)
 - dementing process
- **CT/MRI: ventricular enlargement disproportionate to cortical atrophy and small-vessel ischemic changes**
- **Confirmed by beneficial response to large-volume cerebrospinal fluid drainage (30-50 ml)**

**iNPH
Gait**

**Normal
Gait**

**Parkinson's
Gait**
